## FUEL CELL ELECTROCATALYST OF Pt-Ni-Mn/Fe

### BACKGROUND OF THE INVENTION

#### Field of The Invention

- 5           The present invention relates to metal catalysts, especially to ternary catalysts which comprise platinum, nickel and manganese or iron, which are useful in fuel cell electrodes and other catalytic structures.

#### Background Information

- A fuel cell is an electrochemical device for directly converting the chemical energy  
10   generated from an oxidation-reduction reaction of a fuel such as hydrogen or hydrocarbon-based fuels and an oxidizer such as oxygen gas (in air) supplied thereto into a low-voltage direct current. Thus, fuel cells chemically combine the molecules of a fuel and an oxidizer without burning, dispensing with the inefficiencies and pollution of traditional combustion.
- 15           A fuel cell is generally comprised of a fuel electrode (anode), an oxidizer electrode (cathode), an electrolyte interposed between the electrodes (alkaline or acidic), and means for separately supplying a stream of fuel and a stream of oxidizer to the anode and the cathode, respectively. In operation, fuel supplied to the anode is oxidized, releasing electrons which are conducted via an external circuit to the cathode.
- 20   At the cathode, the supplied electrons are consumed when the oxidizer is reduced. The current flowing through the external circuit can be made to do useful work.

- There are several types of fuel cells, including those having electrolytes of: phosphoric acid, molten carbonate, solid oxide, potassium hydroxide, and proton exchange membrane. A phosphoric acid fuel cell operates at about 160-220 °C, and  
25   preferably at about 190-200 °C. This type of fuel cell is currently being used for multi-megawatt utility power generation and for co-generation systems (i.e., combined heat and power generation) in the 50 to several hundred kilowatts range.

- In contrast, proton exchange membrane fuel cells use a solid proton-conducting polymer membrane as the electrolyte. Typically, the polymer membrane is maintained in  
30   a hydrated form during operation in order to prevent loss of ionic conduction which limits the operation temperature typically to between about 70 and about 120 °C depending on the operating pressure, and preferably below about 100 °C. Proton exchange membrane fuel cells have a much higher power density than liquid electrolyte fuel cells

(e.g., phosphoric acid), and can vary output quickly to meet shifts in power demand. Thus, they are suited for applications such as in automobiles and small scale residential power generation where quick startup is a consideration.

In some applications (e.g., automotive) pure hydrogen gas is the optimum fuel; however, in other applications where a lower operational cost is desirable, a reformed hydrogen-containing gas is an appropriate fuel. A reformed-hydrogen containing gas is produced, for example, by steam-reforming methanol and water at 200-300 °C to a hydrogen-rich fuel gas containing carbon dioxide. Theoretically, the reformat gas consists of 75 vol% hydrogen and 25 vol% carbon dioxide. In practice, however, this gas also contains nitrogen, oxygen, and, depending on the degree of purity, varying amounts of carbon monoxide (up to 1 vol%). Although some electronic devices also reform liquid fuel to hydrogen, in some applications the conversion of a liquid fuel directly into electricity is desirable, as then a high storage density and system simplicity are combined. In particular, methanol is an especially desirable fuel because it has a high energy density, a low cost, and is produced from renewable resources.

For the oxidation and reduction reactions in a fuel cell to proceed at useful rates, especially at operating temperatures below about 300 °C, electrocatalyst materials are typically provided at the electrodes. Initially, fuel cells used electrocatalysts made of a single metal, usually platinum (Pt), palladium (Pd), rhodium (Rh), iridium (Ir), osmium (Os), silver (Ag) or gold (Au) because they are able to withstand the corrosive environment - platinum being the most efficient and stable single-metal electrocatalyst for fuel cells operating below about 300 °C. While these elements were first used in fuel cells in metallic powder form, later techniques were developed to disperse these metals over the surface of electrically conductive supports (e.g., carbon black) to increase the surface area of the electrocatalyst which in turn increased the number of reactive sites leading to improved efficiency of the cell. Nevertheless, fuel cell performance typically declines over time because the presence of electrolyte, high temperatures and molecular oxygen dissolve the electrocatalyst and/or sinter the dispersed electrocatalyst by surface migration or dissolution/re-precipitation.

Although platinum is the most efficient and stable single-metal electrocatalyst for fuel cells, it is costly and an increase in electrocatalyst activity over platinum is necessary for wide scale commercialization of fuel cell technology. The development of cathode fuel cell electrocatalyst materials faces longstanding challenges. The greatest challenge is the improvement of the electrode kinetics of the oxygen reduction reaction.

In fact, sluggish electrochemical reaction kinetics have prevented attaining the thermodynamic reversible electrode potential for oxygen reduction. This is reflected in exchange current densities of around  $10^{-10}$  to  $10^{-12}$  A/cm<sup>2</sup> for oxygen reduction on, for example, Pt at low and medium temperatures. A factor contributing to this phenomenon include the fact that the desired reduction of oxygen to water is a four-electron transfer reaction and typically involves breaking a strong O-O bond early in the reaction. In addition, the open circuit voltage is lowered from the thermodynamic potential for oxygen reduction due to the formation of peroxide and possible platinum oxides which inhibit the reaction. A second challenge is the stability of the oxygen electrode (cathode) during long-term operation. Specifically, a fuel cell cathode operates in a regime in which even the most unreactive metals are not completely stable. Thus, alloy compositions which contain non-noble metal elements may have a rate of corrosion which would negatively impact the projected lifetime of a fuel cell. The corrosion may be more severe when the cell is operating near open circuit conditions (which is the most desirable potential for thermodynamic efficiency).

Electrocatalyst materials at the anode also face challenges during fuel cell operation. Specifically, as the concentration of carbon monoxide (CO) rises above about 10 ppm in the fuel the surface of the electrocatalyst can be rapidly poisoned. As a result, platinum (by itself) is a poor electrocatalyst if the fuel stream contains carbon monoxide (e.g., reformed-hydrogen gas typically exceeds 100 ppm). Liquid hydrocarbon-based fuels (e.g., methanol) present an even greater poisoning problem. Specifically, the surface of the platinum becomes blocked with the adsorbed intermediate, carbon monoxide (CO). It has been reported that H<sub>2</sub>O plays a key role in the removal of such poisoning species in accordance with the following reactions:

As indicated by the foregoing reactions, the methanol is adsorbed and partially oxidized by platinum on the surface of the electrode (1). Adsorbed OH, from the hydrolysis of water, reacts with the adsorbed CO to produce carbon dioxide and a proton (2,3). However, platinum does not form OH species well at the potentials fuel cell electrodes operate (e.g., 200 mV-1.5 V). As a result, step (3) is the slowest step in the sequence, limiting the rate of CO removal, thereby allowing poisoning of the electrocatalyst to

occur. This applies in particular to a proton exchange membrane fuel cell which is especially sensitive to CO poisoning because of its low operating temperatures.

One technique for increasing electrocatalytic cathodic activity during the reduction of oxygen and electrocatalytic anodic activity during the oxidation of hydrogen is to  
5 employ an electrocatalyst which is more active, corrosion resistant, and/or more poison tolerant. For example, increased tolerance to CO has been reported by alloying platinum and ruthenium at a 50:50 atomic ratio (see, D. Chu and S. Gillman, J. Electrochem. Soc. 1996, 143, 1685). The electrocatalysts proposed to date, however, leave room for further improvement.

#### 10 BRIEF SUMMARY OF THE INVENTION

Briefly, therefore, the present invention is directed to a ternary catalyst for use in oxidation or reduction reactions, the ternary catalyst comprising platinum, nickel, and manganese or iron, with the concentration of platinum being less than 50 atomic percent.

15 The present invention is also directed to a supported electrocatalyst powder for use in electrochemical reactor devices, the supported electrocatalyst powder comprising a ternary catalyst comprising platinum, nickel, and manganese or iron, with the concentration of platinum being less than 50 atomic percent and electrically conductive support particles upon which the ternary catalyst is dispersed.

20 The present invention is also directed to a fuel cell electrode, the fuel cell electrode comprising electrocatalyst particles and an electrode substrate upon which the electrocatalyst particles are deposited, the electrocatalyst particles comprising a ternary catalyst comprising platinum, nickel, and manganese or iron, with the concentration of platinum being less than 50 atomic percent.

25 The present invention is also directed to a fuel cell comprising an anode, a cathode, a proton exchange membrane between the anode and the cathode, and a ternary catalyst comprising platinum, nickel, and manganese or iron, with the concentration of platinum being less than 50 atomic percent for the catalytic oxidation of a hydrogen-containing fuel or the catalytic reduction of oxygen.

30 The present invention is also directed to a method for the electrochemical conversion of a hydrogen-containing fuel and oxygen to reaction products and electricity in a fuel cell comprising an anode, a cathode, a proton exchange membrane therebetween, a ternary catalyst comprising platinum, nickel, and manganese or iron,

with the concentration of platinum being less than 50 atomic percent, and an electrically conductive external circuit connecting the anode and cathode, the method comprising contacting the hydrogen-containing fuel or the oxygen and the ternary catalyst to catalytically oxidize the hydrogen-containing fuel or catalytically reduce the oxygen.

- 5       The present invention is also directed to an unsupported ternary catalyst layer on a surface of a electrolyte membrane or an electrode, said unsupported ternary catalyst layer comprising platinum, nickel, and manganese or iron.

The foregoing and other features and advantages of the present invention will become more apparent from the following description and accompanying figures.

#### 10    BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

FIG. 1 is a schematic structural view showing members of a fuel cell.

FIG. 2 is a cross-sectional side view of a fuel cell.

FIG. 3 is a photograph of an electrode array comprising thin-film alloy compositions deposited on individually addressable electrodes prepared as described in

- 15   Example 1.

#### DETAILED DESCRIPTION OF THE INVENTION

The present invention is directed to a ternary, metal-containing substance having electrocatalytic activity for use in, for example, fuel cells (e.g., an electrocatalyst). In one embodiment the ternary, metal-containing substance is an alloy of the components.

- 20   However, it is to be noted that the substance (e.g., electrocatalyst) may be a mixture of discrete amounts of the components (e.g., a mixture of metal powders or a mixture of deposits), wherein a discrete amount of the components may comprise a single component or a combination of components (e.g., an alloy).

- In general, it is desirable to decrease the concentration of noble metals  
25   (especially platinum) to reduce the cost of an electrocatalytic alloy. However, as the concentrations of noble metals are decreased, the electrocatalyst alloy may become more susceptible to corrosion, and/or the activity may be diminished. Thus, it is desirable to achieve the most activity per weight percent of noble metals without compromising, for example, the life cycle of the fuel cell in which the electrocatalyst is  
30   placed (see, end current density / weight fraction of platinum as set forth in Tables A -C, infra). Additionally, the composition of the present invention is preferably optimized to

limit noble metal concentration while improving corrosion resistance and/or activity, as compared to platinum.

The present invention is thus directed to a ternary metal-containing substance (e.g., alloy or catalyst) that comprises platinum, nickel and manganese or iron, wherein  
5 the concentration of platinum is less than 50 atomic percent. Furthermore, the ternary substance of the present invention comprises amounts of platinum, nickel and manganese or iron which are sufficient for the metals, present therein, to play a role in the catalytic activity and/or crystallographic structure of, for example, the alloy. Stated another way, the concentrations of platinum, nickel and manganese or iron are such that  
10 the presence of the metals would not be considered an impurity. For example, when present, the concentrations of each of platinum, nickel and manganese or iron are at least about 0.1, 0.5, 1, or even 5 atomic percent.

Accordingly, in addition to comprising less than 50 atomic percent platinum (e.g., in some embodiment the concentration is less than about 45, about 40, about 30, about  
15 20 or even about 10 atomic percent), in at least some embodiments the ternary catalyst of the present invention may comprise less than about 70, about 60 or about 50 atomic percent nickel. In some embodiments the concentration of manganese, when present, is less than about 70, about 60 or about 50 atomic percent. In some embodiment the concentration of iron, when present, is less than about 60, about 50 or about 40 atomic  
20 percent.

In some embodiments the concentration of platinum may range from about 5 to less than 50 atomic percent, from about 10 to less than 45 atomic percent, or from about 20 to less than 40 atomic percent. In these or other embodiments, the concentrations of nickel and, when present, manganese may each independently range from about 10 to  
25 about 70 atomic percent, from about 20 to about 60 atomic percent, or from about 30 to about 50 atomic percent. Additionally, in these or other embodiments, when iron is present the concentration may independently range from about 5 to about 60 atomic percent, from about 10 to about 50 atomic percent, or from about 15 to about 40 atomic percent.

30 In this regard it is to be noted that in one embodiment the substance of the present invention consists essentially of the foregoing metals (e.g., it most likely will contain some degree of impurities that do not play a role in the catalytic activity and/or crystallographic structure of the catalyst). However, in other embodiments it is possible that the substance may comprise other constituents as intentional additions. For

example, many metal alloys may comprise oxygen and/or carbon, either as an impurity or as a desired alloy constituent. In view of the foregoing, the alloys of the present invention, while maintaining the same relative amounts of the constituents disclosed herein (i.e., platinum, manganese, cobalt), may comprise less than 100 percent of the disclosed atoms. Thus, in several embodiments of the present invention the total concentration of the disclosed atoms is greater than about 70, 80, 90, 95, or 99 atomic percent of the substance (e.g., electrocatalyst alloy).

#### Pt-Ni-Fe alloy electrocatalyst compositions

In one embodiment the present invention the ternary metal-containing substance (e.g., alloy or catalyst) comprises platinum, nickel, and iron, wherein the concentration of platinum is less than 50 atomic percent. In another embodiment the concentration of platinum is between about 15 and about 35 atomic percent. In yet another embodiment the concentration of platinum is between about 20 and about 30 atomic percent. In one embodiment the concentration of nickel is between about 50 and about 70 atomic percent. In another embodiment the concentration of nickel is between about 55 and about 65 atomic percent. In one embodiment the concentration of iron is between about 5 and about 20 atomic percent iron. In another embodiment the concentration of iron is between about 10 and about 15 atomic percent iron. Additionally, in one or more embodiments, the sum of nickel and iron may range from greater than 50 to about 80 atomic percent, or about 60 to about 70 atomic percent.

In another embodiment the present invention is directed to a ternary catalyst or alloy comprising from about 30 to less than 50 atomic percent platinum, from about 10 to about 30 atomic percent nickel, and from about 30 to about 50 atomic percent iron. In yet another embodiment the concentration of platinum is from about 35 to less than 45 atomic percent, the concentration of nickel is from about 15 to about 25 atomic percent, and the concentration of iron is from about 35 to about 45 atomic percent.

Specific Pt-Ni-Fe alloy compositions which have been found to exhibit a greater oxygen reduction activity than a platinum standard (i.e., Electrode 56 of Table A, *infra*) are the alloys  $\text{Pt}_{40}\text{Ni}_{20}\text{Fe}_{40}$  and  $\text{Pt}_{40}\text{Ni}_{40}\text{Fe}_{20}$  (i.e., Electrode Numbers 36 and 6, respectively, of Tables A and B, *infra*). Additional specific alloy compositions which have been found to exhibit a greater oxygen reduction than a platinum standard are the alloys  $\text{Pt}_{25}\text{Ni}_{63}\text{Fe}_{12}$ ,  $\text{Pt}_{45}\text{Ni}_{22}\text{Fe}_{33}$ ,  $\text{Pt}_{60}\text{Ni}_{20}\text{Fe}_{20}$ , and  $\text{Pt}_{67}\text{Ni}_{22}\text{Fe}_{11}$  (i.e., Electrode Numbers 43, 46, 38, and 48 of Table B). Still more specific alloy compositions which have been found to

exhibit a greater oxygen reduction than a platinum standard are the alloys  $\text{Pt}_{44}\text{Ni}_{18}\text{Fe}_{38}$ ,  $\text{Pt}_{38}\text{Ni}_{21}\text{Fe}_{41}$ ,  $\text{Pt}_{42}\text{Ni}_{19}\text{Fe}_{39}$ ,  $\text{Pt}_{39}\text{Ni}_{19}\text{Fe}_{42}$ ,  $\text{Pt}_{27}\text{Ni}_{60}\text{Fe}_{13}$  (i.e., Powders HFC 144, 145, 166, 167, 170, 171, and 178 of Table D, *infra*).

#### Pt-Ni-Mn alloy electrocatalyst compositions

- 5 In one embodiment the present invention the ternary metal-containing substance (e.g., alloy or catalyst) comprises platinum, nickel, and manganese, wherein the concentration of platinum is less than 50 atomic percent. In one embodiment the concentration of platinum is between about 20 and less than 50 atomic percent. In another embodiment the concentration of platinum is between about 30 and about 40
- 10 atomic percent. In one embodiment the concentration of nickel is between about 20 and about 60 atomic percent. In another embodiment the concentration of nickel is between about 30 and about 40 atomic percent. In one embodiment the concentration of manganese is between about 20 and about 50 atomic percent. In another embodiment the concentration of manganese is between about 25 and about 45 atomic percent.
- 15 Additionally, in one or more embodiments, the sum of nickel and manganese may range from greater than 50 to about 80 atomic percent, or from about 60 to about 70 atomic percent.

- Specific Pt-Ni-Mn alloy compositions which have been found to exhibit a greater oxygen reduction activity than a platinum standard are the alloys  $\text{Pt}_{60}\text{Ni}_{20}\text{Mn}_{20}$  and
- 20  $\text{Pt}_{40}\text{Ni}_{40}\text{Mn}_{20}$  (i.e., Electrode Numbers 53 and 37, respectively, of Table C, *infra*).

#### Formation of an Electrocatalyst Alloy

- The electrocatalyst alloys of the present invention may be formed by a variety of methods. For example, the appropriate amounts of the constituents may be mixed together and heated to a temperature above the respective melting points to form a
- 25 molten solution of the metals which is cooled and allowed to solidify. Typically, electrocatalysts are used in a powder form to increase the surface area which increases the number of reactive sites and leads to improved efficiency of the cell. Thus, the formed metal alloy may be transformed into a powder after being solidified (e.g., by grinding) or during solidification (e.g., spraying molten alloy and allowing the droplets to
- 30 solidify). It may, however, be advantageous to evaluate alloys for electrocatalytic activity in a non-powder form (see, Examples 1 and 2, *infra*).

To further increase surface area and efficiency, an electrocatalyst alloy for use in a fuel cell may be deposited over the surface of electrically conductive supports (e.g., carbon black). One method for loading an electrocatalyst alloy onto supports typically comprises depositing metal precursor compounds onto the supports, and converting the precursor compounds to metallic form and alloying the metals using a heat-treatment in a reducing atmosphere (e.g., an atmosphere comprising an inert gas such as argon). One method for depositing the precursor compounds involves chemical precipitation of precursor compounds onto the supports. The chemical precipitation method is typically accomplished by mixing supports and sources of the precursor compounds (e.g., an aqueous solution comprising one or more inorganic metallic salts) at a concentration sufficient to obtain the desired loading of the electrocatalyst on the supports and then precipitation of the precursor compounds is initiated (e.g., by adding an ammonium hydroxide solution). The slurry is then typically filtered from the liquid under vacuum, washed with deionized water, and dried to yield a powder that comprises the precursor compounds on the supports.

Another method for depositing the precursor compounds comprises forming a suspension comprising a solution and supports suspended therein, wherein the solution comprises a solvent portion and a solute portion that comprises the constituents of the precursor compound(s) being deposited. The suspension is frozen to deposit (e.g., precipitate) the precursor compound(s) on the particles. The frozen suspension is freeze-dried to remove the solvent portion and leave a freeze-dried powder comprising the supports and the deposits of the precursor compound(s) on the supports.

The temperature reached during the thermal treatment is typically at least as high as the decomposition temperature(s) for the precursor compound(s) and not be so high as to result in degradation of the supports and agglomeration of the supports and/or the electrocatalyst deposits. Typically the temperature is between about 60 °C and about 1100 °C. Inorganic metal-containing compounds typically decompose at temperatures between about 600 and about 1000 °C.

The duration of the heat treatment is typically at least sufficient to substantially convert the precursor compounds to the desired state. In general, the temperature and time are inversely related (i.e., conversion is accomplished in a shorter period of time at higher temperatures and vice versa). At the temperatures typical for converting the inorganic metal-containing compounds to a metal alloy set forth above, the duration of

the heat treatment is typically at least about 30 minutes. In one embodiment, the duration is between about 2 and about 8 hours.

#### Unsupported Catalyst or Alloys in Electrode/Fuel Cell Applications

It is to be noted that, in another embodiment of the present invention, the ternary  
5 metal substance (e.g., catalyst or alloy) may be unsupported; that is, it may be employed  
in the absence of a support particle. More specifically, it is to be noted that in another  
embodiment of the present invention a ternary metal catalyst or alloy, comprising  
platinum, nickel and manganese or iron, may be directly deposited (e.g., sputtered) onto,  
for example, (i) a surface of one or both of the electrodes (e.g., the anode, the cathode  
10 or both), and/or (ii) one or both surfaces of a polyelectrolyte membrane, and/or (iii) some  
other surface, such as a backing for the membrane (e.g., carbon paper).

In this regard it is to be further noted that each component (e.g., metal) of the  
ternary catalyst or alloy may be deposited separately, each for example as a separate  
layer on the surface of the electrode, membrane, etc. Alternatively, two or more  
15 components may be deposited at the same time. Additionally, in the case of an alloy,  
the alloy may be formed and then deposited, or the components thereof may be  
deposited and then the alloy subsequently formed thereon.

Deposition of the component(s) may be achieved using means known in the art,  
including for example known sputtering technique (see, e.g., PCT Application No. WO  
20 99/16137). Generally speaking, however, in one approach sputter-deposition is  
achieved by creating, within a vacuum chamber in an inert atmosphere, a voltage  
differential between a target component material and the surface onto which the target  
component is to be deposited, in order to dislodge particles from the target component  
material which are then attached to the surface of, for example, an electrode or  
25 electrolyte membrane, thus forming a coating of the target component thereon. In one  
embodiment, the components are deposited on a polymeric electrolyte membrane,  
including for example (i) a copolymer membrane of tetrafluoroethylene and  
perfluoropolyether sulfonic acid (such as the membrane material sold under the  
trademark NAFION), (ii) a perfluorinated sulfonic acid polymer (such as the membrane  
30 material sold under the trademark ACIPLEX), (iii) polyethylene sulfonic acid polymers,  
(iv) polyketone sulfonic acids, (v) polybenzimidazole doped with phosphoric acid, (vi)  
sulfonated polyether sulfones, and (vii) other polyhydrocarbon-based sulfonic acid  
polymers.

It is to be noted that the specific amount of each metal or component of the ternary catalyst or alloy may be controlled independently, in order to tailor the composition to a given application. In some embodiments, however, the amount of each deposited component may be less than about 5 mg/cm<sup>2</sup> of surface area (e.g., electrode surface area, membrane surface area, etc.), less than about 1 mg/cm<sup>2</sup>, less than about 0.5 mg/cm<sup>2</sup>, less than about 0.1 mg/cm<sup>2</sup>, or even less than about 0.05 mg/cm<sup>2</sup>. Alternatively, in some embodiments the amount of the deposited component, or alloy, may range from about 0.5 mg/cm<sup>2</sup> to less than about 5 mg/cm<sup>2</sup>, or from about 0.1 mg/cm<sup>2</sup> to less than about 1 mg/cm<sup>2</sup>.

It is to be further noted that the specific amount of each component, and/or the conditions under which the component is deposited, may be controlled in order to control the resulting thickness of the component, or alloy, layer on the surface of the electrode, electrolyte membrane, etc. For example, as determined by means known in the art (e.g., scanning electron microscopy or Rutherford back scattering spectrophotometric method), the deposited layer may have a thickness ranging from several angstroms (e.g., about 2, 4, 6, 8, 10 or more) to several tens of angstroms (e.g., about 20, 40, 60, 80, 100 or more), up to several hundred angstroms (e.g., about 200, 300, 400, 500 or more). Additionally, after all of the components have been deposited, and/or alloyed (or, alternatively, after the alloy has been deposited), the layer of the multi-component metal substance of the present invention may have a thickness ranging from several tens of angstroms (e.g., about 20, 40, 60, 80, 100 or more), up to several hundred angstroms (e.g., about 200, 400, 600, 800, 1000, 1500 or more). Thus, in different embodiments the thickness may be, for example, between about 10 and about 500 angstroms, between about 20 and about 200 angstroms, and between about 40 and about 100 angstroms.

It is to be still further noted that in embodiments wherein a ternary catalyst or alloy (or the components thereof) are deposited as a thin film on the surface of, for example, an electrode or electrolyte membrane, the composition of the deposited catalyst or alloy may be as previously described herein. Alternatively, however, the ternary catalyst or alloy may comprise more than 50 atomic percent platinum when employed in the absence of a support particle (e.g., a carbon support particle). For example, in such embodiment the concentration of platinum may be about 70 atomic percent, about 65 atomic percent, about 60 atomic percent, or even about 55 atomic percent. Further, the concentration of platinum may range from about 10 to about 70 atomic percent, or from

about 20 to about 60 atomic percent. In such instance, the concentrations of nickel and manganese or iron may range from, for example: (i) about 20 to about 60 atomic percent nickel, or about 30 to about 50 atomic percent nickel; (ii) about 10 to about 50 atomic percent iron, or from about 20 to about 40 atomic percent; and, (iii) about 10 to about 50  
5 atomic percent manganese, or from about 20 to about 40 atomic percent manganese.

### Incorporation of the Electrocatalyst Compositions in a Fuel Cell

Although the alloy compositions of the present invention can be used in any type of fuel cell (e.g., phosphoric acid, molten carbonate, solid oxide, potassium hydroxide, and proton exchange membrane), they are particularly suited for use in proton exchange  
10 membrane fuel cells. As shown in FIGS. 1 and 2, a fuel cell, generally indicated **21**, comprises a fuel electrode (anode) **2** and an air electrode, oxidizer electrode (cathode) **3**. In between the electrodes **2** and **3**, a proton exchange membrane **1** serves as an electrolyte and it is usually a strongly acidic ion exchange membrane such as a perfluorosulphonic acid-based membrane. Preferably, the proton exchange membrane  
15 **1**, the anode **2**, and the cathode **3** are integrated into one body to minimize contact resistance between the electrodes and the proton exchange membrane. Current collectors **4** and **5** engage the anode and the cathode, respectively. A fuel chamber **8** and an air chamber **9** contain the respective reactants and are sealed by sealants **6** and **7**, respectively.

20 In general, electricity is generated by hydrogen-containing fuel combustion (i.e., the hydrogen-containing fuel and oxygen react to form water, carbon dioxide and electricity). This is accomplished in the above-described fuel cell by introducing the hydrogen-containing fuel **F** into the fuel chamber **8**, while oxygen **O** (preferably air) is introduced into the air chamber **9**, whereby an electric current can be immediately  
25 transferred between the current collectors **4** and **5** through an outer circuit (not shown). Ideally, the hydrogen-containing fuel is oxidized at the anode **2** to produce hydrogen ions, electrons, and possibly carbon dioxide gas. The hydrogen ions migrate through the strongly acidic proton exchange membrane **1** and react with oxygen and electrons transferred through the outer circuit to the cathode **3** to form water. If the hydrogen-  
30 containing fuel **F** is methanol, it is preferably introduced as a dilute acidic solution to enhance the chemical reaction, thereby increasing power output (e.g., a 0.1 M methanol/0.5 M sulfuric acid solution).

To prevent the loss of ionic conduction in the proton exchange membranes, they typically remain hydrated during operation of the fuel cell. As a result, the material of the proton exchange membrane is typically selected to be resistant to dehydration at temperatures up to between about 100 and about 120 °C. Proton exchange membranes

5 usually have reduction and oxidation stability, resistance to acid and hydrolysis, sufficiently low electrical resistivity (e.g.,  $<10 \Omega\text{-cm}$ ), and low hydrogen or oxygen permeation. Additionally, proton exchange membranes are usually hydrophilic. This ensures proton conduction (by reversed diffusion of water to the anode), and prevents the membrane from drying out thereby reducing the electrical conductivity. For the sake

10 of convenience, the layer thickness of the membranes is typically between 50 and 200  $\mu\text{m}$ . In general, the foregoing properties are achieved with materials which have no aliphatic hydrogen-carbon bonds, which, for example, are achieved by replacing hydrogen with fluorine or by the presence of aromatic structures; the proton conduction results from the incorporation of sulfonic acid groups (high acid strength). Suitable

15 proton-conducting membranes also include perfluorinated sulfonated polymers such as NAFION and its derivatives produced by E.I. du Pont de Nemours & Co., Wilmington, Delaware. NAFION is based on a copolymer made from tetrafluoroethylene and perfluorovinylether, and is provided with sulfonic groups working as ion-exchanging groups. Other suitable proton exchange membranes are produced with monomers such

20 as perfluorinated compounds (e.g., octafluorocyclobutane and perfluorobenzene), or even monomers with C—H bonds which, in a plasma polymer, do not form any aliphatic H atoms which could constitute attack sites for oxidative breakdown.

The electrodes of the present invention comprise the electrocatalyst compositions of the present invention and an electrode substrate upon which the electrocatalyst is

25 deposited. In one embodiment the electrocatalyst alloy is directly deposited on the electrode substrate. In another embodiment the electrocatalyst alloy is supported on electrically conductive supports and the supported electrocatalyst is deposited on the electrode substrate. The electrode may also comprise a proton conductive material that is in contact with the electrocatalyst. The proton conductive material may facilitate

30 contact between the electrolyte and the electrocatalyst, and may thus enhance fuel cell performance. Preferably, the electrode is designed to increase cell efficiency by enhancing contact between the reactant (i.e., fuel or oxygen), the electrolyte and the electrocatalyst. In particular, porous or gas diffusion electrodes are typically used since they allow the fuel/oxidizer to enter the electrode from the face of the electrode exposed

to the reactant gas stream (back face), and the electrolyte to penetrate through the face of the electrode exposed to the electrolyte (front face), and reaction products, particularly water, to diffuse out of the electrode.

- The electrically conductive support particles typically comprise an inorganic material such as carbon. However, the support particles may comprise an organic material such as an electrically conductive polymer (see, U.S. Pat. Appln. 2002/0132040 A1). Carbon supports may be predominantly amorphous or graphitic and they may be prepared commercially, or specifically treated to increase their graphitic nature (e.g., heat treated at a high temperature in vacuum or in an inert gas atmosphere) thereby increasing corrosion resistance. For example, it may be oil furnace black, acetylene black, graphite paper, carbon fabric, or carbon aerogel. A carbon aerogel preferably has an electrical conductivity of between  $10^{-2}$  and  $10^3 \Omega^{-1} \cdot \text{cm}^{-1}$  and a density of between 0.06 and 0.7 g/cm<sup>3</sup>; the pore size is between 20 and 100 nm (porosity up to about 95%). Carbon black support particles may have a Brunauer, Emmett and Teller (BET) surface area up to about 2000 m<sup>2</sup>/g. It has been reported that satisfactory results are achieved using carbon black support particles having a high mesoporous area, e.g., greater than about 75 m<sup>2</sup>/g (see, Catalysis for Low Temperature Fuel Cells Part 1: The Cathode Challenges, T.R. Ralph and M.P. Hogarth, Platinum Metals Rev., 2002, 46, (1), p. 3-14). Experimental results to date indicate that a surface area of about 500 m<sup>2</sup>/g is preferred.
- Preferably, the proton exchange membrane, electrodes, and electrocatalyst materials are in contact with each other. This is typically accomplished by depositing the electrocatalyst either on the electrode, or on the proton exchange membrane, and then placing the electrode and membrane in contact. The alloy electrocatalysts of this invention can be deposited on either the electrode or the membrane by a variety of methods, including plasma deposition, powder application (the powder may also be in the form of a slurry, a paste, or an ink), chemical plating, and sputtering. Plasma deposition generally entails depositing a thin layer (e.g., between 3 and 50  $\mu\text{m}$ , preferably between 5 and 20  $\mu\text{m}$ ) of an electrocatalyst composition on the membrane using low-pressure plasma. By way of example, an organic platinum compound such as trimethylcyclopentadienylplatinum is gaseous between  $10^{-4}$  and 10 mbar and can be excited using radio-frequency, microwaves, or an electron cyclotron resonance transmitter to deposit platinum on the membrane. According to another procedure, electrocatalyst powder is distributed onto the proton exchange membrane surface and integrated at an elevated temperature under pressure. If, however, the amount of

electrocatalyst particles exceeds about  $2 \text{ mg/cm}^2$  the inclusion of a binder such as polytetrafluoroethylene is common. Further, the electrocatalyst may be plated onto dispersed small support particles (e.g., the size is typically between 20 and 200 Å, and more preferably between about 20 and 100 Å). This increases the electrocatalyst

5 surface area which in turn increases the number of reaction sites leading to improved cell efficiency. In one such chemical plating process, for example, a powdery carrier material such as conductive carbon black is contacted with an aqueous solution or aqueous suspension (slurry) of compounds of metallic components constituting the alloy to permit adsorption or impregnation of the metallic compounds or their ions on or in the

10 carrier. Then, while the slurry is stirred at high speed, a dilute solution of suitable fixing agent such as ammonia, hydrazine, formic acid, or formalin is slowly added dropwise to disperse and deposit the metallic components on the carrier as insoluble compounds or partly reduced fine metal particles.

The loading, or surface concentration, of an electrocatalyst on the membrane or

15 electrode is based in part on the desired power output and cost for a particular fuel cell. In general, power output increases with increasing concentration; however, there is a level beyond which performance is not improved. Likewise, the cost of a fuel cell increases with increasing concentration. Thus, the surface concentration of electrocatalyst is selected to meet the application requirements. For example, a fuel cell

20 designed to meet the requirements of a demanding application such as an extraterrestrial vehicle will usually have a surface concentration of electrocatalyst sufficient to maximize the fuel cell power output. For less demanding applications, economic considerations dictate that the desired power output be attained with as little electrocatalyst as possible. Typically, the loading of electrocatalyst is between about

25 0.01 and about  $6 \text{ mg/cm}^2$ . Experimental results to date indicate that in some embodiments the electrocatalyst loading is preferably less than about  $1 \text{ mg/cm}^2$ , and more preferably between about 0.1 and  $1 \text{ mg/cm}^2$ .

To promote contact between the collector, electrode, electrocatalyst, and membrane, the layers are usually compressed at high temperature. The housings of the

30 individual fuel cells are configured in such a way that a good gas supply is ensured, and at the same time the product water can be discharged properly. Typically, several fuel cells are joined to form stacks, so that the total power output is increased to economically feasible levels.

In general, the electrocatalyst compositions and fuel cell electrodes of the present invention may be used to electrocatalyze any fuel containing hydrogen (e.g., hydrogen and reformed-hydrogen fuels). Also, hydrocarbon-based fuels may be used including saturated hydrocarbons such as methane (natural gas), ethane, propane and butane; garbage off-gas; oxygenated hydrocarbons such as methanol and ethanol; and fossil fuels such as gasoline and kerosene; and mixtures thereof.

To achieve the full ion-conducting property of proton exchange membranes, in some embodiments suitable acids (gases or liquids) are typically added to the fuel. For example, SO<sub>2</sub>, SO<sub>3</sub>, sulfuric acid, trifluoromethanesulfonic acid or the fluoride thereof, also strongly acidic carboxylic acids such as trifluoroacetic acid, and volatile phosphoric acid compounds may be used ("Ber. Bunsenges. Phys. Chem.", Volume 98 (1994), pages 631 to 635).

### Fuel Cell Uses

As set forth above, the alloy compositions of the present invention are useful as electrocatalysts in fuel cells which generate electrical energy to perform useful work. For example, the alloy compositions may be used in fuel cells which are in electrical utility power generation facilities; uninterrupted power supply devices; extraterrestrial vehicles; transportation equipment such as heavy trucks, automobiles, and motorcycles (see, Fuji et al., U.S. Pat. No. 6,048,633; Shinkai et al., U.S. Pat. No. 6,187,468; Fuji et al., U.S. Pat. No. 6,225,011; and Tanaka et al., U.S. Pat. No. 6,294,280); residential power generation systems; mobile communications equipment such as wireless telephones, pagers, and satellite phones (see, Prat et al., U.S. Pat. No. 6,127,058 and Kelley et al., U.S. Pat. No. 6,268,077); mobile electronic devices such as laptop computers, personal data assistants, audio recording and/or playback devices, digital cameras, digital video cameras, and electronic game playing devices; military and aerospace equipment such as global positioning satellite devices; and robots.

### Example 1

#### Forming Electrocatalytic Alloys on Individually Addressable Electrodes

The electrocatalyst alloy compositions set forth in Tables A-C, infra, were prepared using the combinatorial techniques disclosed in Warren et al., U.S. Pat. No. 6,187,164; Wu et al., U.S. Pat. No. 6,045,671; Strasser, P., Gorer, S. and Devenney, M., *Combinatorial Electrochemical Techniques For The Discovery of New Fuel-Cell Cathode*

*Materials*, Nayayanan, S.R., Gottesfeld, S. and Zawodzinski, T., eds., Direct Methanol Fuel Cells, Proceedings of the Electrochemical Society, New Jersey, 2001, p. 191; and Strasser, P., Gorer, S. and Devenney, M., *Combinatorial Electrochemical Strategies For The Discovery of New Fuel-Cell Electrode Materials*, Proceedings of the International

- 5 Symposium on Fuel Cells for Vehicles, 41st Battery Symposium, The Electrochemical Society of Japan, Nagoya 2000, p. 153. For example, an array of independent electrodes (with areas of between about 1 and 3 mm<sup>2</sup>) may be fabricated on inert substrates (e.g., glass, quartz, sapphire alumina, plastics, and thermally treated silicon). The individual electrodes were located substantially in the center of the substrate, and
- 10 were connected to contact pads around the periphery of the substrate with wires. The electrodes, associated wires, and contact pads were fabricated from a conducting material (e.g., titanium, gold, silver, platinum, copper or other commonly used electrode materials).

- Specifically, the alloy compositions set forth in Tables A-C were prepared using a
- 15 photolithography/RF magnetron sputtering technique (GHz range) to deposit thin-film alloys on arrays of 64 individually addressable electrodes. A quartz insulating substrate was provided and photolithographic techniques were used to design and fabricate the electrode patterns on it. By applying a predetermined amount of photoresist to the substrate, photolyzing preselected regions of the photoresist, removing those regions
- 20 that have been photolyzed (e.g., by using an appropriate developer), depositing a layer of titanium about 500 nm thick using RF magnetron sputtering over the entire surface and removing predetermined regions of the deposited titanium (e.g. by dissolving the underlying photoresist), intricate patterns of individually addressable electrodes were fabricated on the substrate.

- 25 Referring to FIG. 3, the fabricated array 20 consisted of 64 individually addressable electrodes 21 (about 1.7 mm in diameter) arranged in an 8 x 8 square that were insulated from each other (by adequate spacing) and from the substrate 24 (fabricated on an insulating substrate), and whose interconnects 22 and contact pads 23 were insulated from the electrochemical testing solution (by the hardened photoresist or
- 30 other suitable insulating material).

After the initial array fabrication and prior to depositing the electrocatalyst alloys for screening, a patterned insulating layer covering the wires and an inner portion of the peripheral contact pads, but leaving the electrodes and the outer portion of the peripheral contact pads exposed (preferably approximately half of the contact pad is

covered with this insulating layer) was deposited. Because of the insulating layer, it is possible to connect a lead (e.g., a pogo pin or an alligator clip) to the outer portion of a given contact pad and address its associated electrode while the array is immersed in solution, without having to worry about reactions that can occur on the wires or peripheral contact pads. The insulating layer was a hardened photoresist, but any other suitable material known to be insulating in nature could have been used (e.g., glass silica, alumina, magnesium oxide, silicon nitride, boron nitride, yttrium oxide, or titanium dioxide).

Following the creation of the titanium coated array, a steel mask having 64 holes (1.7 mm in diameter) was pressed onto the substrate to prevent deposition of sputtered material onto the insulating resist layer. The deposition of the electrocatalyst alloys was also accomplished using RF magnetron sputtering and a two shutter masking system as described by Wu et al. which enable the deposition of material onto 1 or more electrodes at a time. Each individual thin-film electrocatalyst alloy is created by a super lattice deposition method. For example, when preparing a ternary alloy electrocatalyst composition, metals M1, M2 and M3 are to be deposited and alloyed onto one electrode. First, a metal M1 sputter target is selected and a thin film of M1 having a defined thickness is deposited on the electrode. This initial thickness is typically from about 3 to about 12 Å. After this, metal M2 is selected as the sputter target and a layer of M2 is deposited onto the layer of M1. The thickness of M2 layer is also from about 3 to about 12 Å. The thicknesses of the deposited layers are in the range of the diffusion length of the metal atoms (e.g., about 10 to about 30 Å) which allows in-situ alloying of the metals. Then, a layer of M3 is deposited onto the M1-M2 alloy forming a M1-M2-M3 alloy film. As a result of the three deposition steps, an alloy thin-film (9 - 25 Å thickness) of the desired stoichiometry is created. This concludes one deposition cycle. In order to achieve the desired total thickness of a cathode electrocatalysts material, deposition cycles are repeated as necessary which results in the creation of a super lattice structure of a defined total thickness (typically about 700 Å). Although the number, thickness (stoichiometry) and order of application of the individual metal layers may be determined manually, it is desirable to utilize a computer program to design an output file which contains the information necessary to control the operation of the sputtering device during the preparation of a particular library wafer (i.e., array). One such computer program is the LIBRARY STUDIO software available from Symyx Technologies, Inc. of Santa Clara, California and described in European Patent No.

1080435 B1. The compositions of several as sputtered alloy compositions were analyzed using x-ray fluorescence (XRF) to confirm that they were consistent with desired compositions (chemical compositions determined using x-ray fluorescence are within about 5% of the actual composition).

- 5        Arrays were prepared to evaluate the specific alloy compositions set forth in Tables A-C below. On each array one electrode consisted essentially of platinum and it served as an internal standard for the screening operation. Additionally, the results for the alloys may be evaluated against an external platinum standard comprising an array of 64 platinum electrodes in which the oxygen reduction activity of the 64 platinum
- 10       electrodes averaged  $-0.35 \text{ mA/cm}^2$  at  $+0.1 \text{ V}$  vs. a mercury/mercury sulfate electrode to determine the experimental error of the oxygen reduction test.

## Example 2

## Screening Alloys for Electrocatalytic Activity

- 20 The alloy compositions set forth in Tables A-C (set forth above) that were synthesized on arrays according to the method set forth in Example 1 were screened according to one and/or two protocols (set forth below) for electrochemical reduction of molecular oxygen to water to determine relative electrocatalytic activity against the internal and/or external platinum standard. The first protocol was used to screen all the
- 25 alloy compositions set forth in Table A (as indicated therein). The second protocol was developed to better reflect the conditions under which a catalyst would be subjected to in an actual fuel cell. The second protocol was used to test several of the Pt-Ni-Mn and the Pt-Ni-Fe alloy compositions that were also tested according to the first protocol. These alloy compositions and test results are set forth above in Tables B and C and the
- 30 protocol used for a particular composition is also indicated therein. As indicated in Tables A-C, certain similar alloy compositions had greater activities than the platinum standard when tested according to the second protocol in contrast to lesser activities when tested according to the first protocol (e.g., Pt<sub>25</sub>Ni<sub>63</sub>Fe<sub>12</sub> and Pt<sub>40</sub>Ni<sub>40</sub>Mn<sub>20</sub>). As a result such alloy compositions are of particular interest.

- 35 In general, the array wafers were assembled into an electrochemical screening cell and a screening device established an electrical contact between the 64 electrode

electrocatalysts (working electrodes) and a 64-channel multi channel potentiostat used for the screening. Specifically, each wafer array was placed into a screening device such that all 64 spots are facing upward and a tube cell body that was generally annular and having an inner diameter of about 2 inches (5 cm) was pressed onto the upward  
5 facing wafer surface. The diameter of this tubular cell was such that the portion of the wafer with the square electrode array formed the base of a cylindrical volume while the contact pads were outside the cylindrical volume. A liquid ionic solution (electrolyte) was poured into this cylindrical volume and a common counter electrode (i.e., platinum gauze), as well as a common reference electrode (e.g., mercury/mercury sulfate  
10 reference electrode (MMS)), were placed into the electrolyte solution to close the electrical circuit.

### First Protocol

During the first protocol a rotator shaft with blades was also placed into the electrolyte to provide forced convection-diffusion conditions during the screening. The  
15 rotation rate was typically between about 300 to about 400 rpm. Depending on the screening experiment either argon or pure oxygen was bubbled through the electrolyte during the measurements. Argon served to remove  $O_2$  gas in the electrolyte to simulate  $O_2$ -free conditions used for the initial conditioning of the electrocatalysts. The introduction of pure oxygen served to saturate the electrolyte with oxygen for the oxygen  
20 reduction reaction. During the screening, the electrolyte was maintained at 60 °C and the rotation rate was constant. Three groups of tests were performed to screen the activity of the electrocatalysts. The electrolyte (1 M  $HClO_4$ ) was purged with argon for about 20 minutes prior to the electrochemical measurements. The first group of tests comprised cyclic voltammetric measurements while purging the electrolyte with argon.  
25 Specifically, the first group of tests comprised:

- a potential sweep from about OCP to about +0.3 V to about -0.63 V and back to about +0.3 V at a rate of about 20 mV/s;
- twelve consecutive potential sweeps from OCP to about +0.3 V to about -0.7 V and back to about +0.3 V at a rate of about 200 mV/s; and  
30
- a potential sweep from about OCP to about +0.3 V to about -0.63 V and back to about +0.3 V at a rate of about 20 mV/s.

The electrolyte was then purged with oxygen for approximately 30 minutes. The following second group of tests were performed while continuing to purge with oxygen:

- a. measuring the open circuit potential (OCP) for a minute; then, starting at OCP the voltage was swept down to about -0.4 V at a rate of about 10 mV/s;
- b. measuring the OCP for a minute; then applying a potential step from OCP to about +0.1 V while measuring the current for about 5 minutes; and
- c. measuring the OCP for a minute; then applying a potential step from OCP to about +0.2 V while monitoring the current for about 5 minutes.

The third group of tests comprised a repeat of the second group of tests after about one hour from completion of the second group of tests. The electrolyte was continually stirred and purged with oxygen during the waiting period. All the foregoing test voltages are with reference to a mercury/mercury sulfate (MMS) electrode.

### Second Protocol

- During the second protocol a rotator shaft with blades was also placed into the electrolyte to provide forced convection-diffusion conditions during the screening. The rotation rate was typically between about 300 to about 400 rpm. Depending on the screening experiment either argon or pure oxygen was bubbled through the electrolyte during the measurements. Argon served to remove O<sub>2</sub> gas in the electrolyte to simulate O<sub>2</sub>-free conditions used for the initial conditioning of the electrocatalysts. The introduction of pure oxygen served to saturate the electrolyte with oxygen for the oxygen reduction reaction. During the screening, the electrolyte was maintained at 60 °C and the rotation rate was constant. Three groups of tests were performed to screen the activity of the electrocatalysts. The electrolyte (0.5 M H<sub>2</sub>SO<sub>4</sub>) was purged with argon for about 20 minutes prior to the electrochemical measurements. Similar to the first protocol, the new protocol comprised of three groups of experimental tests. The first group of tests were cyclic voltammetric scans under oxygen-free conditions that served as an electrochemical cleaning and pretreatment procedure. The second and third groups of tests were linear potential scan tests and chronoamperometric step tests that were also performed in parallel. The first group of tests applied to all the catalysts on the array in parallel comprised cyclic voltammetric measurements while purging the electrolyte with argon. Specifically, the first group of tests comprised:
- a. a potential sweep from about OCP to about +0.3 V to about -0.63 V and back to about +0.3 V at a rate of about 20 mV/s;
  - b. seventy-five consecutive potential sweeps from OCP to about +0.3 V to about -0.7 V and back to about +0.3 V at a rate of about 200 mV/s; and

- c. a potential sweep from about OCP to about +0.3 V to about -0.63 V and back to about +0.3 V at a rate of about 20 mV/s.

The shape of the cyclic voltammetric (CV) profile of the Pt standard catalyst as obtained in test c) was compared to an external standard CV profile obtained from a Pt thin-film

- 5 electrode that had been pretreated until a stable CV was obtained. If the test c resulted in a similar cyclic voltammogram, the first group of experiments was considered completed. If the shape of the cyclic voltammogram of test c did not result in a standard Pt CV behavior, the tests b and c were repeated until the Pt standard catalyst showed the desired standard voltammetric profile. This way, it was ensured that the Pt standard
- 10 catalyst showed a stable and well-defined oxygen reduction activity in subsequent experiments. The electrolyte was then purged with oxygen for approximately 30 minutes. The following second group of tests were performed while continuing to purge with oxygen:

- a. measuring the open circuit potential (OCP) for a minute; then, the potential
- 15 was stepped to -0.4 V, held for a minute, and was then swept up to about +0.4 V at a rate of about 10 mV/s;
- b. measuring the OCP for a minute; then applying a potential step from OCP to about +0.1 V while measuring the current for about 5 minutes; and
- c. measuring the OCP for a minute; then applying a potential step from OCP
- 20 to about +0.2 V while monitoring the current for about 5 minutes.

The third group of tests comprised a repeat of the second group of tests after about one hour from completion of the second group of tests. The electrolyte was continually stirred and purged with oxygen during the waiting period. All the foregoing test voltages are with reference to a mercury/mercury sulfate (MMS) electrode.

- 25 The specific alloy compositions set forth in Tables A-C were prepared and screened in accordance with the above-described methods and the results are set forth therein. The screening results in Tables A-C are for the third test group steady state currents at +0.1 V MMS. The current value reported (End Current Density) is the result of averaging the last three current values of the chronoamperometric test normalized for
- 30 geometric surface area.

### Example 3

#### Synthesis of Supported Electrocatalyst Alloys

The synthesis of  $\text{Pt}_{40}\text{Ni}_{20}\text{Fe}_{40}$  and  $\text{Pt}_{25}\text{Ni}_{63}\text{Fe}_{12}$  alloys (see, Table D, Target Catalyst Comp., *infra*) on carbon support particles was attempted according to different process conditions in order to evaluate the performance of the alloys while in a state that is typically used in fuel cell. To do so, the alloy component precursors were deposited or precipitated on supported platinum powder (i.e., platinum nanoparticles supported on carbon black particles). Platinum supported on carbon black is commercially available from companies such as Johnson Matthey, Inc., of New Jersey and E-Tek Div. of De-Nora, N.A., Inc., of Somerset, New Jersey. Such supported platinum powder is available with a wide range of platinum loading. The supported platinum powder used in this example had a nominal platinum loading of about 40 percent by weight, a platinum surface area of between about 150 and about 170  $\text{m}^2/\text{g}$  (determined by CO adsorption), a combined carbon and platinum surface area between about 350 and about 400  $\text{m}^2/\text{g}$  (determined by  $\text{N}_2$  adsorption), and an average particle size of less than about 0.5 nm (determined by sizing screen).

Referring to Table D, the electrocatalyst alloys corresponding to  $\text{Pt}_{44}\text{Ni}_{18}\text{Fe}_{38}$ ,  $\text{Pt}_{38}\text{Ni}_{21}\text{Fe}_{41}$ ,  $\text{Pt}_{42}\text{Ni}_{18}\text{Fe}_{39}$ ,  $\text{Pt}_{39}\text{Ni}_{19}\text{Fe}_{42}$ , and  $\text{Pt}_{27}\text{Ni}_{60}\text{Fe}_{13}$  were formed on carbon support particles using a freeze-drying precipitation method. The freeze-drying method comprised forming a precursor solution comprising the desired metal atoms in the desired concentrations. For example, to prepare the target  $\text{Pt}_{40}\text{Ni}_{20}\text{Fe}_{40}$  alloy compositions which had a final nominal platinum loading of about 17.7 percent by weight (HFC 144, 145, 170, and 171) about 0.029g of  $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  was dissolved in about 5 ml  $\text{H}_2\text{O}$ . Next, about 0.080g of  $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  was dissolved in the previous solution resulting in a yellow clear solution. To prepare the target  $\text{Pt}_{40}\text{Ni}_{20}\text{Fe}_{40}$  alloy compositions which had a final nominal platinum loading of about 32.0 percent by weight (HFC 166 and 167) about 0.055 g of  $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  was dissolved in about 5 ml  $\text{H}_2\text{O}$ . Next, about 0.153 g of  $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  was dissolved in the previous solution resulting in a yellow clear solution. To prepare the target  $\text{Pt}_{25}\text{Ni}_{63}\text{Fe}_{12}$  alloy compositions (HFC 177 and 178) about 0.144 g of  $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  was dissolved in about 5 ml  $\text{H}_2\text{O}$ . Next, about 0.038 g of  $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  was dissolved in the previous solution resulting in an olive-green clear solution.

Referring to Table D, the HFC 166 and 167 solutions were introduced into separate HDPE (High Density Poly Ethylene) vials containing about 0.200g of supported

platinum powder which had a final nominal platinum loading of about 32.2 percent by weight resulting in a black suspension. The HFC 144, 145, 166, 167, 170, and 171 solutions were introduced into separate HDPE (High Density Poly Ethylene) vials containing about 0.200g of supported platinum powder which had a final nominal  
5 platinum loading of about 17.7 percent by weight resulting in a black suspension. The suspensions were homogenized by immersing a probe of a BRANSON SONIFIER 150 into the vial and sonicating the mixture for about 1 minute at a power level of 3.

The vials containing the homogenized suspensions were then immersed in a liquid nitrogen bath for about 3 minutes to solidify the suspensions. The solid  
10 suspensions were then freeze-dried for about 24 hours using a LABONCO FREEZE DRY SYSTEM (Model 79480) to remove the solvent. The tray and the collection coil of the freeze dryer were maintained at about 26 °C and about -48 °C, respectively, while evacuating the system (the pressure was maintained at about 0.15 mbar). After freeze-drying, each vial contained a powder comprising the supported platinum powder, and  
15 molybdenum, nickel, tungsten, tin, and/or iron precursors deposited thereon.

The recovered precursor powders were then subjected to a heat treatment to reduce the precursors to their metallic state, and to alloy the metals with each other and the platinum on the carbon black particles. One particular heat treatment comprised heating the powder in a quartz flow furnace with an atmosphere comprising about 6% H<sub>2</sub>  
20 and 94% Ar using a temperature profile of room temperature to about 40 °C at a rate of about 5 °C/min; holding at about 40 °C for 2 hours; increasing the temperature to about 200 °C at a rate of 5 °C/min; holding at about 200 °C for two hours; increasing the temperature at a rate of about 5 °C/min to about 600, 700 or 900 °C; holding at a max temperature of about 600, 700 or 900 °C for a duration of about one, two, or seven  
25 hours (indicated in Table D); and cooling down to room temperature.

In order to determine the actual composition of the supported electrocatalyst alloys, the differently prepared alloys (e.g., by composition variation or by heat treatment variation) were subjected to EDS (Electron Dispersive Spectroscopy) elemental analysis. The EDS was performed one sample powders that were compressed into 6 mm  
30 diameter pellets with a thickness of about 1 mm. The target alloy composition and actual composition for the prepared supported electrocatalyst alloys are also set forth in Table D.

Table D

Powder Name	Target Catalyst Comp.	Max Alloying Temp for a duration (°C / hrs)	Actual Catalyst Comp.	Target Pt Loading (wt%)	Measured Pt Loading (wt%)	Log Pt Mass Activity at +0.15 V MMS	Pt Mass Activity at +0.15 V MMS (mA/mg Pt)	Relative performance at +0.15 V MMS	Catalyst Mass Activity at 0.15 V MMS (mA/mg)

#### Example 4

##### Evaluating the Electrocatalytic Activity of Supported Electrocatalysts

The supported alloy electrocatalysts set forth in Table D and formed according to Example 3 were subjected to electrochemical measurements to evaluate their activities.

- 5 For the evaluation, the supported alloy electrocatalysts were applied to a rotating disk electrode (RDE) as is commonly used in the art (see, Rotating disk electrode measurements on the CO tolerance of a high-surface area Pt/Vulcan carbon fuel cell electrocatalyst, Schmidt et al., Journal of the Electrochemical Society (1999), 146(4), 1296-1304; and Characterization of high-surface-area electrocatalysts using a rotating
- 10 disk electrode configuration, Schmidt et al., Journal of the Electrochemical Society (1998), 145(7), 2354-2358). Rotating disk electrodes are a relatively fast and simple screening tool for evaluating supported electrocatalysts with respect to their intrinsic electrolytic activity for oxygen reduction (e.g., the cathodic reaction of a fuel cell).

- The rotating disk electrode was prepared by depositing an aqueous-based ink
- 15 that comprises the support electrocatalyst and a NAFION solution on a glassy carbon disk. The concentration of electrocatalyst powder in the NAFION solution was about 1 mg/mL. The NAFION solution comprised the perfluorinated ion-exchange resin, lower aliphatic alcohols and water, wherein the concentration of resin is about 5 percent by weight. The NAFION solution is commercially available from the ALDRICH catalog as
- 20 product number 27,470-4. The glassy carbon electrodes were 5 mm in diameter and were polished to a mirror finish. Glassy carbon electrodes are commercially available, for example, from Pine Instrument Company of Grove City, Pennsylvania. An aliquot of 10  $\mu$ L electrocatalyst suspension was added to the carbon substrate and allowed to dry at a temperature between about 60 and 70 °C. The resulting layer of NAFION and
- 25 electrocatalyst was less than about 0.2  $\mu$ m thick. This method produced slightly different platinum loadings for each electrode made with a particular suspension, but the variation was determined to be less than about 10 percent by weight.

- After being dried, the rotating disk electrode was immersed into an electrochemical cell comprising an aqueous 0.5 M  $\text{H}_2\text{SO}_4$  electrolyte solution maintained
- 30 at room temperature. Before performing any measurements, the electrochemical cell was purged of oxygen by bubbling argon through the electrolyte for about 20 minutes. All measurements were taken while rotating the electrode at about 2000 rpm, and the measured current densities were normalized either to the glassy carbon substrate area or to the platinum loading on the electrode. Two groups of tests were performed to

screen the activity of the supported electrocatalysts. The first group of tests comprised cyclic voltammetric measurements while purging the electrolyte with argon. Specifically, the first group comprised:

- a. two consecutive potential sweeps starting from OCP to about +0.35V then to about -0.65V and back to OCP at a rate of about 50 mV/s;
- b. two hundred consecutive potential sweeps starting from OCP to about +0.35V then to about -0.65V and back to OCP at a rate of about 200 mV/s; and
- c. two consecutive potential sweeps starting from OCP to about +0.35V then to about -0.65V and back to OCP at a rate of about 50 mV/s.

The second test comprised purging with oxygen for about 15 minutes followed by a potential sweep test for oxygen reduction while continuing to purge the electrolyte with oxygen. Specifically, potential sweeps from about -0.45 V to +0.35 V were performed at a rate of about 5 mV/s to evaluate the initial activity of the electrocatalyst as a function of potential and to create a geometric current density plot. The electrocatalysts were evaluated by comparing the diffusion corrected activity at 0.15 V. All the foregoing test voltages are with reference to a mercury/mercury sulfate electrode. Also, it is to be noted that the oxygen reduction measurements for a glassy carbon RDE without an electrocatalyst did not show any appreciable activity within the potential window.

The above-described supported electrocatalyst alloy compositions were evaluated in accordance with the above-described method and the results are set forth in Table D. The alloy compositions  $\text{Pt}_{44}\text{Ni}_{18}\text{Fe}_{38}$ ,  $\text{Pt}_{38}\text{Ni}_{21}\text{Fe}_{41}$ ,  $\text{Pt}_{42}\text{Ni}_{19}\text{Fe}_{39}$ ,  $\text{Pt}_{39}\text{Ni}_{19}\text{Fe}_{42}$ , and  $\text{Pt}_{27}\text{Ni}_{60}\text{Fe}_{13}$  exhibited oxygen reduction activities greater than that of carbon supported platinum. The results of the evaluation also indicate, among other things, that it may take numerous iterations to develop a set of parameters for producing the target alloy composition. Also evidenced by the data, is that activity can be adjusted by changes in the processing conditions. For example, despite having similar amounts of the metals, the HFC 171 electrocatalyst had a significantly higher activity than the HFC 145 electrocatalyst. This difference in activity may be due to several factors such as alloy homogeneity (e.g., an alloy, as defined below, may have regions in which the constituent atoms show a presence or lack of order, i.e., regions of solid solution within an ordered lattice, or some such superstructure), changes in the lattice parameter due to changes in the average size of component atoms, changes in particle size, and changes in crystallographic structure/symmetry. The ramifications of structure and symmetry

changes are often difficult to predict. Pt and Ni have a face-centered cubic (fcc) structure whereas Fe often crystallizes in a body-centered cubic (bcc) structure; the structure of Mn is more complex and is often dependent on temperature and synthesis factors. Pt-Fe alloys crystallize in structures from primitive cubic to primitive tetragonal, dependent on composition while Pt-Ni alloys may form complete solid solutions based on the structural similarity of the end members. Clearly, symmetry variations are to be expected across a multi-component compositional range. Thus, the ternary alloys may be expected to crystallize in a similar fashion to the previously described structures in a composition-dependent manner. For example, in the Pt-Fe system, as the amount of iron added to platinum increases, the lattice of the resulting alloy may be expected to change from an fcc lattice to a tetragonal primitive lattice. More specifically, the possibility exists that as the relative ratio of metal (in this case Fe) to platinum goes from 0 to 1, an fcc-based solid solution first occurs (e.g., Fe and Pt may mix randomly within some concentration limits, or under some specific synthesis conditions), and out of this solid solution an ordered phase may gradually crystallize (e.g.,  $\text{Pt}_3\text{Fe}$ , primitive cubic structure) only to return to a solid solution (disordered alloy) and again back to an ordered phase (now with either a primitive or face-centered tetragonal structure) as the formula  $\text{PtFe}$  is achieved. Symmetry changes (e.g., those associated with the changes from a cubic face-centered structure to a primitive tetragonal structure) may result in significant changes in the x-ray diffraction pattern. These changes may also be accompanied by more subtle changes in lattice parameters that may be indicative of the resulting changes in the size of the respective metal constituents. For example, the 12-coordinate metallic radii of platinum, nickel, cobalt, iron, and manganese are 1.39 Å, 1.25 Å, 1.25 Å, 1.26 Å, and 1.37 Å respectively, and as metals are substituted for platinum, the average metal radius, and consequently the observed lattice parameter of a disordered alloy may be expected to contract or expand accordingly. Thus, in the case of disordered alloys, the average radius may be used as an indicator of lattice changes as a function of stoichiometry, or alternatively, as an indicator of stoichiometry based on observed diffraction patterns. However, while the average radii may be useful as a general rule, experimental results are typically expected to conform only in a general manner because local ordering, significant size disparity between atoms, significant changes in symmetry, and other factors may produce results that are inconsistent with expectations. This may be particularly true in the case of ordered alloys where an increase in the directionality of bonding may occur.

An interpretation of XRD analysis for the foregoing supported alloys is set forth below. Interpretation of XRD analyses can be subjective, and therefore, the following conclusions are not intended to be limiting. The predicted change in the average radius for the  $\text{Pt}_{44}\text{Ni}_{18}\text{Fe}_{37}$  alloys (HFC 144 and 145) was a contraction of 5.1% vs. platinum.

- 5 The XRD determined contraction of HFC 144 was about 3.5%, however, excess nickel was also observed. XRD of 145 displayed less excess nickel, however in this case the onset of ordering, similar to PtFe, was observed. The predicted change in the average radius for the  $\text{Pt}_{42}\text{Ni}_{19}\text{Fe}_{39}$  alloys (HFC 166 and 167) was a contraction of 5.4% vs. platinum. The observed change, however, was only -3.0% and significant amounts of
- 10 excess nickel were also observed. The predicted change in the average radius for the  $\text{Pt}_{39}\text{Ni}_{19}\text{Fe}_{42}$  alloys (HFC 170 and 171) was a contraction of 5.6% vs. platinum. The observed change was -3.5% and virtually no excess nickel was observed. The predicted change in the average radius for the  $\text{Pt}_{27}\text{Ni}_{60}\text{Fe}_{13}$  alloys (HFC 177 and 178) was a contraction of 7.1% vs. platinum. The observed change was -5.3%. HFC 177
- 15 displays a significant amount of excess nickel while HFC 178 shows much less.

- In view of the foregoing, for a particular electrocatalyst composition a determination of the optimum conditions is preferred to produce the highest activity for that particular composition. For example, the starting materials used to synthesize the alloy may play a role in the activity of the synthesized alloy. Specifically, using
- 20 something other than a metal nitrate salt solution to supply the metal atoms may result in different activities. Different methods of synthesis (e.g., chemical precipitation and freeze-drying impregnation) may result in differing activities due to both differences in particle size and/or differences in stoichiometric control. Heat treatment parameters such as atmosphere, time, temperature, etc. may also need to be optimized. This
- 25 optimization may involve balancing competing phenomena. For example, increasing the heat treatment temperature is generally known to improve the reduction of a metal salt to a metal which typically increases activity; however, it also tends to increase the size of the electrocatalyst alloy particle and decrease surface area, which decreases electrocatalytic activity.

### Definitions

Activity is defined as the maximum sustainable, or steady state, current (Amps) obtained from the electrocatalyst, when fabricated into an electrode, at a given electric potential (Volts). Additionally, because of differences in the geometric area of electrodes, when comparing different electrocatalysts, activity is often expressed in terms of current density ( $A/cm^2$ ).

An alloy is a mixture comprising two or more metals. An alloy may be described as a solid solution in which the solute and solvent atoms (the term solvent is applied to the metal that is in excess) are arranged at random, much in the same way as a liquid solution may be described. If some solute atoms replace some of those of the solvent in the structure of the latter, the solid solution may be defined as a substitutional solid solution. Alternatively, an interstitial solid solution is formed if a smaller atom occupies the interstices between the larger atoms. Combinations of the two types are also possible. Furthermore, in certain solid solutions, some level of regular arrangement may occur under the appropriate conditions resulting in a partial ordering that may be described as a superstructure. These solid solutions may have characteristics that may be distinguishable through characterization techniques such as XRD. Significant changes in XRD may be apparent due to changes in symmetry, if more complete ordering occurs such as that which occurs between Pt metal and  $Pt_3Fe$ . Although the global arrangement of the atoms is extremely similar in both cases, the relationship between the locations of the Pt and Fe atoms is now ordered and not random resulting in different diffraction patterns. Further, a homogeneous alloy is a single compound comprising the constituent metals. A heterogeneous alloy comprises an intimate mixture of crystals of individual metals and/or metallic compounds (see, Structural Inorganic Chemistry, A.F. Wells, Oxford University Press, 5<sup>th</sup> Edition, 1995, chapter 29). An alloy, as defined herein, is also meant to include materials which may comprise elements which are generally considered to be non-metallic. For example, some alloys of the present invention may comprise oxygen in atomic, molecular, and/or metallic oxide form. Additionally, some alloys of the present invention may comprise carbon in atomic, molecular, and/or metal carbide form. If present, the amount of oxygen and/or carbon in the alloy is typically at what is generally considered to be a low level (e.g., less than about 5 weight percent), however higher concentrations are also possible (e.g., up to about 10 weight percent).

It is to be understood that the above description is intended to be illustrative and not restrictive. Many embodiments will be apparent to those of skill in the art upon reading the above description. The scope of the invention should therefore be determined not with reference to the above description alone, but should be determined  
5 with reference to the claims and the full scope of equivalents to which such claims are entitled.

WHAT IS CLAIMED IS

1. A ternary catalyst for use in oxidation or reduction reactions, the ternary catalyst comprising platinum, nickel, and manganese or iron, with the concentration of platinum being less than 50 atomic percent.

2. The ternary catalyst of claim 1 consisting essentially of platinum, nickel, and manganese or iron.

3. The ternary catalyst of claim 1 wherein the concentration of platinum is between about 15 and about 35 atomic percent, the nickel is at a concentration that is between 50 and about 70 atomic percent, and the iron is at a concentration that is between about 5 and about 20 atomic percent.

4. The ternary catalyst of claim 1 wherein the concentration of platinum is between about 20 to about 30 atomic percent, the nickel is at a concentration that is between 55 and about 65 atomic percent, and the iron is at a concentration that is between about 10 and about 15 atomic percent.

5. The ternary catalyst of claim 1 wherein the concentration of platinum is between about 30 and less than 50 atomic percent, the nickel is at a concentration that is between about 10 and about 30 atomic percent, and the iron is at a concentration that is between about 30 and about 50 atomic percent.

6. The ternary catalyst of claim 1 wherein the concentration of platinum is between about 35 and less than 45 atomic percent, the nickel is at a concentration that is between about 15 and about 25 atomic percent, and the iron is at a concentration that is between about 35 and about 45 atomic percent.

7. The ternary catalyst of claim 1 wherein the concentration of platinum is between about 20 and less than 50 atomic percent, the nickel is at a concentration that is between about 20 and about 60 atomic percent, and the manganese is at a concentration that is between about 20 and about 50 atomic percent.

8. The ternary catalyst of claim 1 wherein the concentration of platinum is between about 30 and less than 40 atomic percent, the nickel is at a concentration that is between about 30 and about 40 atomic percent, and the manganese is at a concentration that is between about 25 and about 45 atomic percent.

9. The ternary catalyst as in any one of claims 1-8 wherein the ternary catalyst is an alloy.

10. A supported electrocatalyst powder for use in electrochemical reactor devices, the supported electrocatalyst powder comprising the ternary catalyst as in any one of claims 1-9 and electrically conductive support particles upon which the ternary catalyst is dispersed.

11. The supported electrocatalyst powder of claim 10 wherein the electrically conductive support particles are selected from the group consisting of inorganic supports and organic supports.

12. The supported electrocatalyst powder of claim 11 wherein the electrically conductive support particles are selected from the group consisting of carbon supports and electrically conductive polymer supports.

13. A fuel cell electrode, the fuel cell electrode comprising electrocatalyst particles and an electrode substrate upon which the electrocatalyst particles are deposited, the electrocatalyst particles comprising the ternary catalyst as in any one of claims 1-9.

14. The fuel cell electrode of claim 13 wherein the electrocatalyst particles comprise electrically conductive support particles upon which the ternary catalyst is dispersed.

15. The fuel cell electrode of claim 14 wherein the electrically conductive support particles are selected from the group consisting of carbon supports and electrically conductive polymer supports.

16. A fuel cell comprising an anode, a cathode, a proton exchange membrane between the anode and the cathode, and the ternary catalyst as in any one of claims 1-9 for the catalytic oxidation of a hydrogen-containing fuel or the catalytic reduction of oxygen.

17. The fuel cell of claim 16 wherein the fuel consists essentially of hydrogen.

18. The fuel cell of claim 16 wherein the fuel is a hydrocarbon-based fuel.

19. The fuel cell of claim 16 wherein the fuel comprises methanol.

20. The fuel cell of claim 16 wherein the ternary catalyst is on the surface of the proton exchange membrane and in contact with the anode.

21. The fuel cell of claim 16 wherein the ternary catalyst is on the surface of the anode and in contact with the proton exchange membrane.

22. The fuel cell of claim 16 wherein the ternary catalyst is on the surface of the proton exchange membrane and in contact with the cathode.

23. The fuel cell of claim 16 wherein the ternary catalyst is on the surface of the cathode and in contact with the proton exchange membrane.

24. A method for the electrochemical conversion of a hydrogen-containing fuel and oxygen to reaction products and electricity in a fuel cell comprising an anode, a cathode, a proton exchange membrane therebetween, the ternary catalyst as in any one of claims 1-9, and an electrically conductive external circuit connecting the anode and  
5 cathode, the method comprising contacting the hydrogen-containing fuel or the oxygen and the ternary catalyst to catalytically oxidize the hydrogen-containing fuel or catalytically reduce the oxygen.

25. The method of claim 24 wherein the hydrogen-containing fuel consists essentially of hydrogen.

26. The method of claim 24 wherein the hydrogen-containing fuel is a hydrocarbon-based fuel selected from the group consisting of saturated hydrocarbons, garbage off-gas, oxygenated hydrocarbons, fossil fuels, and mixtures thereof.

27. The method of claim 24 wherein the hydrogen-containing fuel is methanol.

28. An unsupported ternary catalyst layer on a surface of a electrolyte membrane or an electrode, said unsupported ternary catalyst layer comprising platinum, nickel, and manganese or iron.

29. The unsupported ternary catalyst layer of claim 28 wherein said layer has a thickness of about 10 to about 500 angstroms.

30. The unsupported ternary catalyst layer of claim 28 wherein said layer has a thickness of about 20 to about 200 angstroms.

31. The unsupported ternary catalyst layer of claim 28 wherein said layer has a thickness of about 40 to about 100 angstroms.

32. The unsupported ternary catalyst layer of claim 28 wherein said layer has a surface concentration of the unsupported ternary catalyst of less than about 5 mg/cm<sup>2</sup>.

33. The unsupported ternary catalyst layer of claim 28 wherein said layer has a surface concentration of the unsupported ternary catalyst of less than about 1 mg/cm<sup>2</sup>.

34. The unsupported ternary catalyst layer of claim 28 wherein said layer has a surface concentration of the unsupported ternary catalyst ranging from about 0.5 mg/cm<sup>2</sup> to less than about 5 mg/cm<sup>2</sup>.

35. The unsupported ternary catalyst layer of claim 28 wherein said layer has a surface concentration of the unsupported ternary catalyst ranging from about 0.1 mg/cm<sup>2</sup> to less than about 1 mg/cm<sup>2</sup>.

36. The unsupported catalyst layer of any one of claims 28-35 wherein said unsupported ternary catalyst layer has a composition corresponding to the ternary catalyst as in any one of claims 1-9.
